WORKING PAPERS	<p>“Reducing Consumer Inertia in Tobacco Markets” (JMP), with Gaston Lopez We study the equilibrium effects of tobacco control policies. Despite decades-long efforts to discourage smoking, the tobacco industry remains resilient. One of the main reasons is consumers’ attachment to the products they smoke, which we call <i>consumer inertia</i>. We explore two reasons consumers are attached to their products: they get addicted to nicotine and develop lasting brand loyalty to their products. Recently, regulators have proposed some policies that would eliminate the addictive components of cigarettes and others that make consumers less loyal to their brands. Although such policies would directly impact consumers, we must understand firms’ responses to assess their impact on consumption. Consumer inertia introduces dynamic incentives for the firms since future demand depends on current choices. As a result, consumers become a valuable asset for the firm, which modifies how they price, introduce, and discontinue products. To assess the empirical effect of reducing inertia in tobacco markets, we develop a model that accounts for consumers and firm responses: consumers have addiction and loyalty, and firms choose prices and product portfolios. We estimate the model leveraging rich variation from the Uruguayan industry and solve the dynamic game for multiple counterfactual levels of inertia. We find that firms’ responses are unlikely to <i>reverse</i> the direct effect on consumers, even though lowering inertia makes customers more price-responsive and can facilitate entry. The central mechanism is that lowering inertia also discourages firms from investing in attracting customers, who are less likely to repeat consumption choices. Even when the policies do <i>backfire</i>, the effect on consumption remains small because of this countervailing force.</p> <p>“How Governments Engage in Price Discrimination? Evidence from a Large Scale Nationalization”, with Gaston Lopez State-owned enterprises (SOEs) have the potential to correct market failures, but they are also subject to the influence of politics and interest groups. We study this trade-off in the context of the nationalization of the leading gasoline company in Argentina. Descriptive analysis suggests that pricing patterns changed after the nationalization. First, the government charged lower markups on average, exerting less market power. Second, it engaged in less economic price discrimination, reducing the correlation between prices and consumers’ willingness to pay. Third, it engaged in political price discrimination, charging lower prices in provinces that have political connexions with the firm. Motivated by these findings, we develop and estimate a model of supply and demand of gasoline under market power and recover the government’s objective function. We find that public provision leads to welfare gains but is also associated</p>			

with redistributive motives. Compared to a benevolent planner that internalizes the welfare of all consumers and firms equally, the government chooses prices as if it only cares about consumers in provinces with political ties with the firm and middle-income consumers in all provinces. Lastly, we use the model to assess the firm’s response to policy tools, including rules that limit discretion in decision-making and echo existing regulations in government agencies worldwide. We find that rules effectively reduce the influence of politics in pricing but are associated with higher costs: they mitigate half of the welfare gains generated by the nationalization and increase the tax-payers burden by 10%. These findings emphasize the importance of politics and interest groups in shaping governments’ decision-making and the role of SOEs as instruments for redistribution

“Bounding Outcomes in Counterfactual Analysis”, with Mar Reguant

In many economic settings, counterfactual analysis can be difficult for two reasons: (i) we do not know how to compute the equilibrium of the game, or (ii) even if we know how to compute one equilibrium, the game might feature multiple equilibria, which are challenging to characterize exhaustively. We propose a bounding framework to allow for counterfactual analysis even when these problems might arise. The method relies on determining valid (conservative) bounds to counterfactual outcomes that contain any outcome that could be sustained in equilibrium, i.e., any outcome that can be supported by a set of equilibrium constraints. To ensure that all potential solutions are considered, We propose to reframe equilibrium constraints as a relaxed mixed-integer linear program. We show that the framework can also be used to narrow down equilibria by imposing additional equilibrium constraints. We provide examples of static price competition with differentiated products, dynamic games, and multi-unit auctions, three areas where counterfactual analysis faces these challenges.
